

Dear Acme Example Co Hiring Team,

I'm applying for the Platform Engineer role. I've spent the last few years owning the shared backend services other engineers build on top of, which is exactly the scope this role describes.

At Acme Corp, our nightly reconciliation job was a 4-hour cron batch that paged on-call at 2am when it ran long — the constraint was that reconciliation had to stay incremental, not batch, without losing correctness guarantees. I rewrote it as an event-driven pipeline; that cut end-of-day reconciliation time to 20 minutes and stopped being an on-call liability.

I also inherited an on-call rotation averaging 12 pages a week with maybe 2 real incidents. The problem wasn't alert volume, it was signal-to-noise: I tightened thresholds and removed redundant checks, cutting weekly pages by roughly 70%. Both of these are the kind of platform-reliability work your posting calls out directly — cutting alert noise, migrating brittle batch jobs to something more resilient.

I'd welcome the chance to talk about the ledger and job-queue platform and where I could contribute.

Best, Jane Doe
